One-slide overview

(figure credit: arXiv:1205.3933)

- LHC + naturalness \implies SUSY w/ light 3rd gen.
- Gluino pair-production signatures:

```
4 boosted tops + MET
```

- Tagging boosted tops gives us low SM background
- Probe gluino masses up to 1 TeV @ 7 TeV LHC with $\int \mathcal{L} = 30 \text{ fb}^{-1}$

Michael Saelim (Cornell)

SUSY with light 3rd generation

$$\begin{split} \delta m_{H_u}^2|_{\text{stop, LL}} &= -\frac{3}{8\pi^2} \, y_t^2 \left(m_{Q_3}^2 + m_{u_3}^2 + |A_t|^2 \right) \, \ln\!\left(\frac{\Lambda}{\text{TeV}}\right) \\ \delta m_{H_u}^2|_{\text{gluino, LL}} &= -\frac{2}{\pi^2} \, y_t^2 \left(\frac{\alpha_s}{\pi}\right) |M_3|^2 \, \ln^2\!\left(\frac{\Lambda}{\text{TeV}}\right) \end{split}$$

- MSSM w/ degenerate squarks: squarks and gluinos > 1 TeV
 - Fine-tuning, unnatural EWSB
- But not all squarks are equal!
 - Stop @ 1L and gluino @ 2L are the most important for the Higgs
 - Consider models with light 3rd generation squarks and gluinos

< ロト < 同ト < ヨト < ヨト

Papucci, Ruderman, and Weiler (arXiv:1110.6926)

- Reinterpreted results of LHC searches ($\sim 1 {\rm fb}^{-1})$ in terms of MSSM w/ light 3rd gen.
- Stops > 2-300 GeV, Gluinos > 600 GeV

-

- ₹ 🗦 🕨

Simplified model

- Require $m(\tilde{g}) m(\tilde{t})$ and $m(\tilde{t}) m(\tilde{\chi}^0) > m(t)$ to get on-shell tops, and fix $m(\tilde{\chi}^0) = 60$ GeV
- 4 top + MET signal (figure credit: arXiv:1205.3933)
- Boosted tops if mass separation is large enough

イロト 不得下 イヨト イヨト

Update: CMS 4.98fb⁻¹ bounds (arXiv:1205.3933)

Tagging boosted tops

Run Number: 166658, Event Number: 34533931 Date: 2010-10-11 23:57:42 CEST

- Hadronic boosted tops have collimated decay products
- Cluster "fat jets" with $R \sim 1.0$
- Examine jet substructure and invariant mass of subjets

(figure credit: ATLAS-CONF-2011-073)

May 18, 2012 10 / 26

Johns Hopkins Top Tagger

- The first top tagging algorithm
- Kaplan, Rehermann, Schwartz, and Tweedie (arXiv: 0806.0848)
- $\bullet\,$ Favored for tops with pT $\gtrsim 500\,\,{\rm GeV}$
- Three steps:
 - Clustering
 - 2 Declustering
 - Substructure

- 4 同 6 4 日 6 4 日 6

Johns Hopkins Top Tagger: Clustering

- We recluster the jet with C/A into a fat jet of radius R
 - Start out with protojets corresponding to energy deposits in calorimeter cells
 - Iteratively bring together the two closest protojets in $\Delta R = \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2}$ until all remaining protojets are separated by $\Delta R \geq R$
 - We get a tree structure

Johns Hopkins Top Tagger: Declustering

- Iteratively decluster the jet to find up to 4 irreducible subjets
 - Irreducible subjets are hard enough and angularly separated enough
 - User defines pT scale $\delta_p p_T$ (original fat jet) and angular scale δ_r
- Go backwards through C/A tree, splitting subjet j into j_1 and j_2 .

Four cases:

- If j is an indivisible calorimeter cell, j is an irreducible subjet
- If both j₁ and j₂ are softer than the p_T scale or closer than the angular scale, j is an irreducible subjet
- If only j₁ or j₂ is softer than the p_T scale, throw it away and iterate on the harder subjet
- If both j₁ and j₂ are harder than the pT scale, repeat algorithm on each until it finds irreducible subjets

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ ののの

Johns Hopkins Top Tagger: Substructure

- Require either 3 or 4 irreducible subjets
- Require $m_{\rm all \ subjets}$ near $m_{\rm top}$
- Require $m_{2 \text{ subjets}}$ near m_W
- Cut on W helicity angle $\cos \theta_h$

▲ # ↓ ★ ∃ ★

Top tagging

Johns Hopkins Top Tagger: performance

- R = 1.0 anti-kt jets
- $\delta_p = 0.04$
- $\delta_r = 0.19$
- $160 < m_t < 265 \,\,{
 m GeV}$
- $60 < m_W < 120 \text{ GeV}$
- $\cos \theta_h < 0.95$

(BOOST 2010 workshop, arXiv:1012.5412)

50% tag rate, with only a few % mistag rate

Other top taggers

- CMS uses a top tagger based on Johns Hopkins (ex. CMS-EXO-11-006 $Z' \rightarrow t\bar{t}$)
- HEPTopTagger (Plehn, Spannowsky, Takeuchi, Zerwas arXiv:1006.2833)
 - Based on BDRS Mass Drop + Filtering algorithm for 2-body decays
 - Favored for moderately boosted tops (200 GeV $< p_T < 500$ GeV)
- Leptonic top tagging (Plehn, Spannowsky, Takeuchi arXiv:1102.0557)
- N-subjettiness (Thaler, Van Tilburg arXiv:1011.2268, arXiv:1108.2701)

- ∢ ≣ →

Signal simulation

- Gluino pair-production into 4 tops $+ \not E_T$
- We require
 - \geq 4 jets with p_T > 100 GeV,
 - some jets top-tagged,
 - and significant $\not \! E_T$

3

イロト イヨト イヨト

Background simulation

- Irreducible backgrounds:
 - n tops + (4 n) jets
 - n tops + (4 n) jets + leptonic W
 - n tops + (4 n) jets + invisible Z
- Reducible backgrounds:
 - Mistagging light jets as tops
- LO cross sections used: known K-factors are < 1
- p_T and \mathcal{E}_T cut efficiencies computed at parton level
- p_T -dependent tagging efficiencies and mistag rates from the BOOST2010 workshop used (arXiv:1012.5412)
 - Tended to overestimate backgrounds by a factor of 2

Reach at 7 TeV and 30 fb^{-1}

Michael Saelim (Cornell)

May 18, 2012 23 / 26

Going to 14 TeV and 10 fb^{-1}

Michael Saelim (Cornell)

May 18, 2012 24 / 26

However...

- Detector effects/systematics not included
- Larger background samples needed
- QCD 4 $j \not E_T$ tail needs studying
- But, the reach may be underestimated

Conclusion

- SUSY could be hiding if lightest colored super partner is stop
- Boosted top tagging provides excellent coverage of this scenario, including at 7 and 8 TeV
- Further experimental analysis is needed
